1. Introduction

Welcome to Decagon’s AquaLab Pre. AquaLab Pre is a quick, accurate, and reliable instrument for measuring water activity ($a_w$). Whether you are doing research or working on the production line, AquaLab will suit your needs. It is easy to use and provides accurate and timely results. We hope you find this manual informative and helpful in understanding how to maximize the capabilities of your AquaLab Pre.

About this Manual

Included in this manual are instructions for setting up your AquaLab Pre, verifying the calibration of the instrument, preparing samples, and maintaining and caring for your instrument. Please read these instructions before operating your AquaLab to ensure that the instrument performs to its full potential.

Warranty

AquaLab Pre has a 30-day satisfaction guarantee and a one-year warranty on parts and labor. Your warranty is automatically validated upon receipt of the instrument. We will contact you within the first 90 days of your purchase to see how the AquaLab is working for you.
Customer Support

If you ever need assistance with your AquaLab Pre, or if you just have questions or feedback, there are several ways to contact us. Customer Service Representatives are available to speak with you Monday thru Friday, between 7am and 5pm Pacific time.

**NOTE:** If you purchased your AquaLab Pre through a distributor, please contact them for assistance.

**E-mail:**
support@aqualab.com or sales@aqualab.com

**Phone:**
1-509-332-5601

**Fax:**
1-509-332-5158

If contacting us by email or fax, please include as part of your message your instrument’s serial number, your name, address, phone, and fax number.

Seller’s Liability

Seller warrants new equipment of its own manufacture against defective workmanship and materials for a period of three years from date of receipt of equipment (the results of ordinary wear and tear, neglect, misuse, accident and excessive deterioration due to corrosion from any cause are not to be considered a defect); but Seller’s liability for defective parts shall in no event exceed the furnishing of replacement parts Freight on Board the factory where originally manufactured. Material and equipment covered hereby which is not manufactured by Seller shall be covered only by the
warranty of its manufacturer. Seller shall not be liable to Buyer for loss, damage or injuries to persons (including death), or to property or things of whatsoever kind (including, but not without limitation, loss of anticipated profits), occasioned by or arising out of the installation, operation, use, misuse, nonuse, repair, or replacement of said material and equipment, or out of the use of any method or process for which the same may be employed. The use of this equipment constitutes Buyer’s acceptance of the terms set forth in this warranty. There are no understandings, representations, or warranties of any kind, express, implied, statutory or otherwise (including, but without limitation, the implied warranties of merchantability and fitness for a particular purpose), not expressly set forth herein.
2. About AquaLab Pre

AquaLab Pre is a fast and accurate instrument for measuring water activity ($a_w$), giving readings in five minutes or less. Its readings are reliable providing ±0.01$a_w$ accuracy. The instrument is easy to clean and checking calibration is simple.

**AquaLab Pre Instrument Specifications**

- **Water Activity Range:** 0.050 to 1.000
- **Water Activity Accuracy:** ±0.01
- **Water Activity Resolution:** ±0.001
- **Read time:** < 5 min.
- **Sample Temperature Control:** 25°C
- **Sample Temperature Accuracy:** ±0.2°C
- **Sample Temperature Resolution:** 0.1°C
- **Sample Dish Capacity:** 7 ml recommended (15 ml full)
- **Operating Environment:** 4 to 50°C; 0 to 90% Relative Humidity (non-condensing)
- **Case Dimensions:** 24.1 x 22.9 x 8.9 cm
- **Weight:** 3.2 Kg
- **Case Material:** Powder Painted Aluminum
- **Display:** 20 x 2 alphanumeric LCD with backlighting
- **Data Communication:** RS232A compatible, 8-data bit ASCII code, 9600 baud, no parity, 1 stop bit
- **Power:** 110VAC to 220 VAC, 50/60 Hz
- **Warranty:** 1 year parts and labor
About AquaLab Pre

1. on samples with no significant impedance to vapor loss
2. AquaLab is calibrated to a NIST traceable temperature standard.

**AquaLab and Water Activity**

Water activity ($a_w$) is a measurement of the energy status of the water in a system. It indicates how tightly water is “bound”, structurally or chemically, within a substance. Water activity is the relative humidity of air in equilibrium with a sample in a sealed measurement chamber. The concept of water activity is of particular importance in determining product quality and safety. Water activity influences color, odor, flavor, texture and shelf-life of many products. It predicts safety and stability with respect to microbial growth, chemical and biochemical reaction rates, and physical properties. For a more detailed description of water activity as it pertains to products, please refer to Chpt. 3 of this manual, titled “Water Activity Theory”.

**How AquaLab Works**

AquaLab uses the chilled-mirror dewpoint technique to measure the water activity of a sample. In an instrument that uses the dewpoint technique, the sample is equilibrated with the headspace of a sealed chamber that contains a mirror and a means of detecting condensation on the mirror. At equilibrium, the relative humidity of the air in the chamber is the same as the water activity of the sample. In the AquaLab, the mirror temperature is precisely controlled by a thermoelectric (Peltier) cooler. Detection of the exact point at which condensation first appears on the mirror is observed with a photoelectric cell. A beam of light is directed onto
the mirror and reflected into a photodetector cell. The photodetector senses the change in reflectance when condensation occurs on the mirror. A thermocouple attached to the mirror then records the temperature at which condensation occurs. AquaLab then signals you by flashing a green LED and/or beeping. The final water activity and temperature of the sample is then displayed.

In addition to the technique described above, AquaLab uses an internal fan that circulates the air within the sample chamber to reduce equilibrium time. Since both dewpoint and sample surface temperatures are simultaneously measured, the need for complete thermal equilibrium is eliminated, which reduces measurement times to less than five minutes.

**AquaLab and Temperature**

The AquaLab Pre controls temperature to 25°C, making it ideal for the measurement of samples at room temperature. However, samples that are not at room temperature during the read cycle will equilibrate to the temperature of AquaLab before the water activity is displayed. Large temperature differences will cause longer reading times, since a complete and accurate reading will not be made until the sample and the instrument are within 2 degrees of each other. To better help you control the temperature difference between your sample and the instrument, you can access a sample equilibration screen at the main menu that can show the difference in temperature between the sample and chamber block (see chpt. 4).
If tests need to be conducted at temperatures other than 25°C, the temperature control feature can be turned off and the instrument will be at the same temperature as ambient.

**Limitations**

AquaLab’s only major limitation is its ability to accurately measure samples with high concentrations of certain volatiles such as ethanol or propylene glycol, which can co-condense on the surface of the chilled mirror. Not all volatiles react this way, but it is important to note that some volatiles can affect the performance of your instrument. The extent of the effect is both concentration- and matrix-dependent; thus, just because a product contains some ethanol or propylene glycol does not necessarily mean the readings will be erroneous. Therefore, if your sample contains propylene glycol or a high concentration of other volatiles, it is still possible to make accurate readings. Refer to the section titled “Volatile Samples” in on page 40 or contact Decagon for more details.
3. Water Activity Theory

Water is a major component of foods, pharmaceuticals, and cosmetics. Water influences the texture, appearance, taste and spoilage of these products. There are two basic types of water analysis: water content and water activity.

Moisture Content

The meaning of the term moisture content is familiar to most people. It implies a quantitative analysis to determine the total amount of water present in a sample. Primary methods for determining moisture content are loss on drying and Karl Fisher titration, but secondary methods such as infrared and NMR are also used. Moisture content determination is essential in meeting product nutritional labeling regulations, specifying recipes and monitoring processes. However, moisture content alone is not a reliable indicator for predicting microbial responses and chemical reactions in materials. The limitations of moisture content measurement are attributed to differences in the intensity with which water associates with other components.

Water Activity

Water activity is a measure of the energy status of the water in a system, and thus is a far better indicator of perishability than water content. Figure 1 shows how the relative activity of microorganisms, lipids and enzymes relate to water activity. While other fac-
tors, such as nutrient availability and temperature, can affect the relationships, water activity is the best single measure of how water affects these processes.

Water activity of a system is measured by equilibrating the liquid phase water in the sample with the vapor phase water in the headspace and measuring the relative humidity of the headspace. In the AquaLab, a sample is placed in a sample cup which is sealed against a sensor block. Inside the sensor block is a fan, a dew point sensor, a temperature sensor, and an infrared thermometer. The dew point sensor measures the dew point temperature of the air, and the infrared thermometer measures the sample temperature. From these measurements the relative humidity of the headspace is computed as the ratio of dew point temperature saturation vapor pressure to saturation vapor pressure at the sample temperature. When the water activity of the sample and the relative humidity of the air

Fig. 3-1: Water Activity Diagram—adapted from Labuza
are in equilibrium, the measurement of the headspace humidity gives the water activity of the sample. The purpose of the fan is to speed equilibrium and to control the boundary layer conductance of the dew point sensor.

In addition to equilibrium between the liquid phase water in the sample and the vapor phase, the internal equilibrium of the sample is important. If a system is not at internal equilibrium, one might measure a steady vapor pressure (over the period of measurement) which is not the true water activity of the system. An example of this might be a baked good or a multi-component food. Initially out of the oven, a baked good is not at internal equilibrium; the outer surface is at a lower water activity than the center of the baked good. One must wait a period of time in order for the water to migrate and the system to come to internal equilibrium. It is important to remember the restriction of the definition of water activity to equilibrium.

**Temperature Effects**

Temperature plays a critical role in water activity determinations. Most critical is the measurement of the difference between sample and dew point temperature. If this temperature difference were in error by 1°C, an error of up to 0.06aw could result. In order for water activity measurements to be accurate to 0.001, temperature difference measurements need to be accurate to 0.017°C. AquaLab’s infrared thermometer measures the difference in temperature between the sample and the block. It is carefully calibrated to minimize temperature errors, but achieving 0.017°C accuracy is
difficult when temperature differences are large. Best accuracy is therefore obtained when the sample is near chamber temperature.

Another effect of temperature on water activity occurs with samples are near saturation. A sample that is close to $1.0a_w$ and is only slightly warmer than the sensor block will condense water within the block. This will cause errors in the measurement, and in subsequent measurements until the condensation disappears. A sample at $0.75a_w$ needs to be approximately $4^\circ C$ above the chamber temperature to cause condensation. The AquaLab warns the user if a sample is more than $4^\circ C$ above the chamber temperature, but for high water activity samples the operator needs to be aware that condensation can occur if a sample that is warmer than the block is put in the AquaLab.

**Water Potential**

Some additional information may be useful for understanding what water activity is and why it is such a useful measure of moisture status in products. Water activity is closely related to a thermodynamic property called the water potential, or chemical potential ($m$) of water, which is the change in Gibbs free energy ($G$) when water concentration changes. Equilibrium occurs in a system when $m$ is the same everywhere in the system. Equilibrium between the liquid and the vapor phases implies that $m$ is the same in both phases. It is this fact that allows us to measure the water potential of the vapor phase and use that to determine the water potential of the liquid phase. Gradients in $m$ are driving forces for moisture movement. Thus, in an isothermal system, water tends to move from regions of high water potential (high water activity) to regions of
low water potential (low water activity). Water content is not a driving force for water movement, and therefore can not be used to predict the direction of water movement, except in homogeneous materials.

**Factors in Determining Water Potential**

The water potential of the water in a system is influenced by factors that effect the binding of water. They include osmotic, matric, and pressure effects. Typically water activity is measured at atmospheric pressure, so only the osmotic and matric effects are important.

**Osmotic Effects**

Osmotic effects are well known from biology and physical chemistry. Water is diluted when a solute is added. If this diluted water is separated from pure water by a semi-permeable membrane, water tends to move from the pure water side through the membrane to the side with the added solute. If sufficient pressure is applied to the solute-water mixture to just stop the flow, this pressure is a measure of the osmotic potential of the solution. Addition of one mole of an ideal solute to a kilogram of water produces an osmotic pressure of 22.4 atm. This lowers the water activity of the solution from 1.0 to 0.98a_w. For a given amount of solute, increasing the water content of the systems dilutes the solute, decreasing the osmotic pressure, and increasing the water activity. Since microbial cells are high concentrations of solute surrounded by semi-permeable membranes, the osmotic effect on the free energy of the water is important for determining microbial water relations and therefore their activity.
**Matric Effects**
The sample matrix affects water activity by physically binding water within its structure through adhesive and cohesive forces that hold water in pores and capillaries, and to particle surfaces. If cellulose or protein were added to water, the energy status of the water would be reduced. Work would need to be done to extract the water from this matrix. This reduction in energy status of the water is not osmotic, because the cellulose or protein concentrations are far too low to produce any significant dilution of water. The reduction in energy is the result of direct physical binding of water to the cellulose or protein matrix by hydrogen bonding and van der Waal forces. At higher water activity levels, capillary forces and surface tension can also play a role.

**Sorption Isotherms**

**Relating Water Activity to Water Content**
Changes in water content affect both the osmotic and matric binding of water in a product. Thus a relationship exists between the water activity and water content of a product. This relationship is called the sorption isotherm, and is unique for each product. Besides being unique to each product, the isotherm changes depending on whether it was obtained by drying or wetting the sample. These factors need to be kept in mind if one tries to use water content to infer the stability or safety of a product. Typically, large safety margins are built in to water content specifications to allow for these uncertainties.

While the sorption isotherm is often used to infer water activity from water content, one could easily go the other direction and use
the water activity to infer the water content. This is particularly attractive because water activity is much more quickly measured than water content. This method gives particularly good precision in the center of the isotherm. In order to infer water content from water activity, one needs an isotherm for the particular product; produced, ideally, using the process that brings the product to its final water content.

For example, if one were using the AquaLab to monitor the water content of dried potato flakes, one would measure the water activity and water content of potato flakes dried to varying degrees using the standard drying process for those flakes. An isotherm would be constructed using those data, and the water content would be inferred using the measured water activity of samples and that isotherm.

The importance of the concept of water activity of foods, pharmaceuticals, and cosmetics cannot be overly emphasized. Water activity is a measure of the energy status of the water in a system. More importantly, the usefulness of water activity in relation to microbial growth, chemical reactivity, and stability over water content has been shown.
4. Getting Started

Components of your AquaLab Pre

Your AquaLab should have been shipped with the following items:

- AquaLab Pre water activity meter
- Power cord
- RS-232 to USB interface cable
- 100 disposable sample cups
- Operator’s Manual
- Quick Start guide
- Cleaning Kit
- 3 vials each of the following calibration solutions:
  - 0.920$_{aw}$ 2.33 molal NaCl
  - 0.760$_{aw}$ 6.0 molal NaCl
  - 0.500$_{aw}$ 8.57 molal LiCl
  - 0.250$_{aw}$ 13.41 molal LiCl

Choosing a Location

To ensure that your AquaLab Pre operates correctly and consistently, place it on a level surface. This reduces the chance that sample material will spill and contaminate the sample chamber. Also select a location where the temperature remains fairly stable to avoid temperature changes that can affect accuracy. This location should be well away from air conditioner and heater vents, open...
windows, etc. Place the AquaLab in a location where cleanliness can be maintained to prevent contamination of the sample chamber.

**Features**

*Figure 4-1: Front view of AquaLab*

*Figure 4-2: Back view of AquaLab*
Preparing AquaLab for Operation

After finding a good location for your AquaLab, plug the power cord into the back of the unit. Before turning it on, turn the knob to the “OPEN/LOAD” position, pull open the sample drawer and remove the empty disposable sample cup. This empty cup is placed in the drawer to protect it during shipment. Turn the instrument on (see features diagram). The following screens will appear on the LCD.

(Note: The “v 1.0” shown in the above illustration is an example showing the version of operating code used in the instrument. We periodically update the code and add new features, so if your AquaLab shows a version number higher than this, don’t be alarmed.)

Then the screen will automatically shift to the measurement screen shown below which is displaying the water activity ($a_w$) on the top left portion of the screen, and the sample temperature in the lower right.

In order to provide the most accurate readings, your AquaLab should ideally be allowed to warm-up for at least 15 minutes after turning it on. This allows the air inside the AquaLab to equilibrate to the temperature of its surroundings.
AquaLab Pre
5. The Menus

5. The Menus

The Measurement Screen

![Diagram of button options from main menu]

Each time you turn on your AquaLab, the screen above will appear. As mentioned earlier, the water activity and sample temperature are displayed on the screen. On each side of the LCD there are two buttons. Each button performs a different function. Following is a description of the modes and options you may use, and the buttons used to set them.

---

Figure 5-1: diagram of button options from main menu

Changing Languages

The AquaLab comes to you with English as the default on-screen user language. If you prefer not to use English, you can change it...
to one of a variety of other languages: German, French, Spanish, Italian, Swedish, Danish, Norwegian, Czech, Portuguese, Japanese, Polish or Finnish. This is done simply by pressing the upper right button of the instrument while the drawer knob is in the OPEN/LOAD position. You will see the following screen:

Press the upper right key again, and the next language option (German) will appear:

Each time you press the right button, the display will scroll to the next language option. Select the desired language, then press the lower left button to exit.

**Normal Sampling Mode**

The first time you turn on the AquaLab, it will be in normal sampling mode. In this mode, the sample is measured once, after which the instrument notifies you that it is finished with a series of four beeps and a green flashing light. The operator has the ability to change the sampling mode and the audible alarm.
**AquaLab Pre**

*5. The Menus*

**Continuous Mode**

Continuous mode reads your sample continuously until you turn the knob to the OPEN/LOAD position. It will read the sample, display the water activity and sample temperature, then begin another read cycle without turning the knob. Between samples, it will signal you with the green LED flash, accompanied by the beeper (if it is enabled).

To toggle between the normal and continuous modes, press the top left button. The display will show a small “c” to the left of the water activity readings:

![“c” for continuous mode]

*Figure 5-2: Main menu with continuous mode enabled*

If you press the upper left button again, the “c” will disappear and you will be back in normal sampling mode.

**Temperature Equilibration Screen**

To see the temperature difference between your sample and the AquaLab, press the lower right button at the main menu. This
screen can only be accessed when the drawer knob is in the OPEN/LOAD position. The following screen will appear:

\[
\begin{align*}
T_b &= 23.1 \\
T_s - T_b &= 0.125
\end{align*}
\]

This screen shows the temperature difference between the sample (\(T_s\)) and the chamber block (\(T_b\)), allowing you to quickly check if the sample is too hot, which may cause condensation inside the chamber. Press the lower right button to exit.

**System Configuration**

If you press the bottom left button while at the measurement screen, it will bring you to the system configuration menu.

This menu allows you to make minor system changes. From this menu, you can change the audible alarm after each sample or enter the linear offset adjustment menu.
**Completion Notification**

When you are sampling, the AquaLab has two ways of notifying you that the water activity reading is complete: an audible alarm and a flashing green LED, located on the left front corner of the AquaLab’s case. In normal sampling mode, when a sample is started, the LED will flash once, and when it is finished it will flash continuously until the knob is moved to the OPEN/LOAD position (if not operating in continuous mode). You cannot turn off or change the LED flashing functions.

There are three audible alarm options, represented by three icons as shown below.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>🎧 0x</td>
<td>No beeping.</td>
</tr>
<tr>
<td>🎧 4x</td>
<td>Beeps four times, then stops.</td>
</tr>
<tr>
<td>🎧 ∞</td>
<td>Beeps until drawer is opened.</td>
</tr>
</tbody>
</table>

*Figure 5-4: Definition of beeper icons*
The audible alarm can be turned off completely, it can beep momentarily when the sample is finished and then stop, or it can beep continuously until the knob is turned to the OPEN/LOAD position.

**TE SET**
This selection lets you turn the temp control on and off. If on, the instrument will control to 25°C. If off, the instrument will be at ambient temperature.

**EXIT**
You may press the EXIT button (the lower left button) to exit back to the main measurement screen at any time.

**Adjusting for linear offset**
When you need to adjust for linear offset, press the upper right button in the system configuration menu, and you will be brought to the linear offset menu. For more details on linear offset and how to verify for it, please refer to Chapter 7.
6. Cleaning and Maintenance

Keeping your AquaLab clean is vital to maintaining the accuracy of your instrument. Dust and sampling debris can contaminate the sampling chamber and must therefore be regularly cleaned out. To clean your instrument, carefully follow these instructions and refer to the labeled diagram below.

Figure 6-1: View of inside block chamber

**Purpose**

The purpose for the cleaning procedure is to remove grease, dirt and other soluble substances which can absorb/release water during verification, calibration, and/or sample testing. For a smooth
and even dew formation, it requires the mirror to be perfectly clean. If there are any contaminants (e.g. fingerprints) on the mirror, the dew will form unevenly and thus affect the accuracy of the reading.

**Materials Needed**

- A thin plastic rod or other non-metal implement
- Distilled Water
- Isopropyl Alcohol (IPA) or Decagon Cleaning Solution
- Kimwipes®

You may also purchase the AquaLab Cleaning Kit which comes with all the above materials except the Isopropyl Alcohol and Distilled Water.

*NOTE:* Wash your hands with soap and water and/or use clean lab gloves before starting the cleaning procedure. This will prevent oils from contaminating the cleaning materials, the sample chamber and/or the sensors.

**Cleaning the Block and Sensors**

**Accessing the Block**

Turn the power off on your AquaLab (switch in back.) Next, remove the case lid screw located on the back panel. Carefully remove the lid by pulling the back of the lid upward and then sliding the lid back (away from the front of the case) and off. Unscrew the two thumbscrews that secure the sensor block. Unplug the cable with the 20-pin socket that attaches the block to the main cir-
AquaLab Pre
6. Cleaning and Maintenance

circuit board by releasing the two locking levers that are on either side of the socket. Carefully lift the block straight up from its mount. Turn the block over to expose the chamber cavity as shown in the illustration at the beginning of this chapter.

NOTE for Volatiles Block: If cleaning an AquaLab Pre Volatiles Block, follow the cleaning procedures listed below being especially careful not to get cleaning solution or alcohol on the capacitance sensor filter. Repeated exposure of cleaning materials or contaminants to the filter may cause inaccurate readings. If the filter appears contaminated, replace it while being careful not to disturb the sensor behind the filter.

Cleaning Procedure:

Cleaning your AquaLab is a multi-step procedure which involves washing, rinsing, and drying for each specific area as outlined below:

1. Cleaning the Sample Chamber

NOTE: Be extremely careful not to damage the fan blades (see illustration) when cleaning the chamber.

a. Remove any debris that may have collected within or around the sample chamber.

b. Wrap a NEW Kimwipe around the end of the thin plastic rod (spatula) and moisten it with isopropyl alcohol or Decagon Cleaning Solution. NOTE: Do NOT dip a used Kimwipe into your container of IPA or cleaning solution (the IPA or cleaning solution will become contaminated).
AquaLab Pre
6. Cleaning and Maintenance

c. WASH--Clean all surface edges of the samples chamber including the edge where the sample cup seals to the chamber block. You may need to replace the Kimwipe if it becomes too dirty during this process.

d. RINSE--Repeat steps b and c using new Kimwipes with distilled water.

e. DRY--Repeat steps b and c using new, dry Kimwipes to help remove any moisture remaining from the cleaning.

f. Visually inspect the sample chamber for cleanliness. Re-clean if necessary. **NOTE: Do not reuse Kimwipes.**

2. Clean the Mirror

a. Wrap a new Kimwipe around the end of the thin plastic rod (spatula) and moisten it with isopropyl alcohol or Decagon Cleaning Solution.

b. WASH--Swipe the moistened Kimwipe across the mirror once. (A single swipe is usually sufficient to remove contaminants.)

c. RINSE--Repeat steps a-b using new Kimwipes moistened with distilled water instead of cleaning solution.

d. DRY--Repeat steps a-b using new, dry Kimwipes to help remove any moisture remaining from the cleaning.

e. Visually inspect mirror for cleanliness. Re-clean if necessary.
3. Clean the Thermopile and Optical Sensor

a. Wrap a new Kimwipe around the end of the thin plastic rod (spatula) and moisten it with isopropyl alcohol or Decagon Cleaning Solution.

b. WASH--Swipe the moistened Kimwipe across thermopile and optical sensor. (A single swipe is usually sufficient to remove contaminants.)

c. RINSE--Repeat steps a-b using new Kimwipes moistened with distilled water instead of cleaning solution.

d. DRY--Repeat steps a-b but use a new, dry Kimwipe to help remove any moisture remaining from the cleaning.

e. Visually inspect the thermopile and optical sensor for cleanliness. Re-clean if necessary.

4. Additional Drying Time

a. Visually inspect the sample chamber and sensors for contaminants, including moisture. If necessary, repeat the cleaning process using new Kimwipes.

b. Let stand for about 5 minutes to ensure the sample chamber is dry.

Checking Calibration

After you have cleaned the chamber and other parts of your AquaLab, it is important to check the instrument’s performance in
order to correct for any linear offset that may have occurred during the cleaning process.

Before you check the instrument we recommend that you run a sample of the activated charcoal pellets provided in your AquaLab cleaning kit. This cleans the air inside the chamber, helping it come back to a stable sampling environment.

Verify the linear offset against known calibration standards according to the procedure described in the next chapter. If a linear offset has occurred, refer to “adjust for linear offset” section in Chapter 7 for directions on how to correct for linear offset. If, after adjusting for linear offset, your instrument is still not reading samples correctly, please contact Decagon for support.
7. Verification and Calibration

It is important to verify AquaLab’s water activity calibration against known standards to guarantee optimal performance and accuracy. Decagon recommends verification daily, once per shift, or before each use (if used infrequently).

**Water Activity Verification**

AquaLab uses the chilled-mirror dewpoint technique to determine water activity. Because this is a primary measurement of relative humidity, no calibration is necessary; however, it is important to check for linear offset periodically. The components used by the instrument to measure water activity are subject to contamination which may affect the AquaLab’s performance. When this occurs, it changes the accuracy of the instrument. This is what is called a “linear offset.” Therefore, frequent verification assures you that your AquaLab is performing correctly. Linear offset is checked by using two different calibration standards.

**Calibration Standards**

Calibration standards are specially prepared salt solutions having a specific molality and water activity constant which are accurately measurable. The calibration standards that were sent with your initial shipment are very accurate and readily available from Decagon. Using calibration standards to verify accuracy can greatly reduce preparation errors. For these reasons, we recommend using stan-
Performance Calibration Standards come in six water activity levels: 1.000, 0.984, 0.920, 0.760, 0.500, and 0.250\(a_w\). The standards are produced under a strict quality assurance regime. Please contact Decagon Devices to order additional standards via sales@decagon.com or 509-332-5601.

NOTE: If you need to obtain a Material Safety Data Sheet (MSDS) for any of these standards, a printable version is available on our website at www.decagon.com/msds.

To use a calibration standard, remove the twist top and pour the contents into an AquaLab sample cup. If for some reason you cannot obtain Decagon’s calibration standards and need to make a saturated salt solution for verification, refer to Appendix A.
**AquaLab Pre**
7. Verification and Calibration

**Calibration**

**When to Verify for Linear Offset**
Linear offset should be checked against two known calibration standards either daily, once per shift or before each use. Linear offset should never be verified solely against distilled water, since it does not give an accurate representation of the linear offset. For batch processing, the instrument should be checked regularly against a known standard of similar water activity. It is also a good idea to check the offset with a standard of similar water activity when the general water activity range of your sample is changing. Checking the water activity of a standard solution will alert you to the possibility of unit contamination or shifts in the linear offset from other causes.

*NOTE:* The calibration process is the same for both the dewpoint and volatiles block except that the accuracy for the capacitance sensor in the volatiles block is ± 0.02 $a_w$.

**Verification**
To verify for linear offset of your AquaLab, do the following:
1. Choose a calibration standard that is close to the water activity of the sample you are measuring. *NOTE:* The AquaLab needs to warm up for approximately 15 minutes to make accurate readings.

2. Empty a vial of the chosen calibration standard into a sample cup and place it in the AquaLab’s sample drawer. Make sure that your standard is as close to the instrument temperature as possible.

*NOTE:* Make sure the rim of the sample cup is clean.
3. Carefully slide the drawer closed and turn the knob to the READ position.

4. Take two readings. The water activity readings should be within $\pm 0.01a_w$ of the given value for the calibration standard. See Appendix B for the correct water activity value of Decagon’s standards at temperatures other than 25°C.

5. If your AquaLab is reading within $\pm 0.01a_w$ of the calibration standard, choose a second calibration standard that would border the range of water activity you plan to test. For example, if you plan to test for water activity readings ranging between 0.713 and 0.621 you should use the 6.0M, NaCl ($0.76a_w$) standard for your first verification and the 8.57M LiCl ($0.50a_w$) for the second verification.

6. Prepare a sample cup of the second calibration standard and make two readings. The water activity reading for the second calibration standard should be within $\pm 0.01a_w$.

7. If either one of the verifications is not correct, it is probably due to contamination of the sensor chamber. For cleaning instructions, see Chapter 6. After cleaning, repeat verification from step two.

8. If you are consistently getting readings outside the water activity of your first calibration standard by more than $\pm 0.01a_w$, a linear offset has probably occurred. In this case, adjust the reading on the calibration standard to its correct value as outlined in the next section.
Adjusting for Linear Offset

1. Once you are certain that a linear offset has occurred, enter the system configuration menu by pressing the lower left button from the measurement screen. Press the upper right button in the system configuration menu to enter the linear offset menu. You will be guided through the linear offset routine.

2. If you wish to continue, press the button next to “yes.” To return to the measurement screen, press the button next to “no.” After selecting “yes,” the following screen will appear:

   place standard in drawer and read

3. Empty the whole vial of a calibration standard into a sample cup. We recommend using the 6.0M NaCl (0.76$_{w}$). Do not adjust for the offset using distilled water. Ensure the rim and outside of the cup are clean. Place the prepared sample cup in the AquaLab’s sample drawer.

   NOTE: The same calibration standard may be used to verify and adjust the linear offset.

4. Close the drawer, being especially careful so the solution won’t splash or spill and contaminate the chamber.

5. Turn the drawer knob to the READ position to make a water activity reading.
NOTE: If you decide at this point not to continue with the linear offset program, just return the knob to the OPEN/LOAD position and remove the sample.

After your AquaLab has finished sampling the calibration standard, it will display the following screen:

![Screen showing 0.760 and adjustment buttons]

use these buttons to adjust the value

6. Adjust the water activity value to its proper value for the particular calibration standard you are measuring by pressing the up or down buttons until the correct value is displayed. When the value is correct, press the Exit button to store this new value.

NOTE: This is the only menu where these buttons can change the linear offset, so you won’t hurt anything by pressing these buttons in other menus.

7. Re-measure the calibration standard again in the normal sampling mode. It should read the proper value at a given temperature for that calibration standard (see Appendix B).

8. Measure the water activity of a second calibration standard according to the verification procedure described above. If both verification readings are within ±0.01aw then the instrument is ready to begin testing.
If you still have incorrect verification readings after cleaning the chamber and/or adjusting for linear offset, contact Decagon for further instructions at support@aqualab.com or 509-332-5601. If you purchased your AquaLab from one of our international distributors, please contact them for local service and support.

*See the verification section in the operator’s manual

Figure 7-1: This flowchart is a graphical representation of the directions given above for checking for linear offset.
8. Sample Preparation

Your AquaLab will continually provide accurate water activity measurements as long as its internal sensors are not contaminated by improperly-prepared samples. Careful preparation and loading of samples will lengthen time between cleanings and will help you avoid cleaning and downtime.

Preparing the Sample

To prepare a sample, follow these steps:

1. **Make sure that the sample to be measured is homogeneous.** Multi-component samples (e.g., muffins with raisins) or samples that have outside coatings (like deep-fried, breaded foods) can be measured, but may take longer to equilibrate. For samples like these, AquaLab may take more than five minutes to give an accurate reading, or may require multiple readings of the same sample. Measuring the water activity of these types of product is discussed in detail later in this chapter (see Materials Needing Special Preparation).

2. **Place the sample in a disposable sample cup, completely covering the bottom of the cup, if possible.** AquaLab is able to accurately measure a sample that does not (or cannot) cover the bottom of the cup. For example, raisins only need to be placed in the cup and not flattened to cover the bottom. A larger sample surface area increases instrument efficiency by
providing more stable infrared sample temperatures. It also speeds up the reading by shortening the time needed to reach vapor equilibrium.

3. **Do not fill the sample cup more than half full. Overfilled cups will contaminate the sensors in the sensor chamber!** Filling the sample cup will not make the readings faster or more accurate. There only needs to be enough sample in the cup to allow the water in the sample to equilibrate with the water in the vapor phase and not change the moisture content of the sample. There is a minimum amount of sample needed; therefore, covering the bottom of the sample cup is normally enough.

4. **Make sure that the rim and outside of the sample cup are clean.** Wipe any excess sample material from the rim of the cup with a clean tissue. Material left on the rim or the outside of the cup will contaminate the sensor chamber and be transferred to subsequent samples. The rim of the cup forms a vapor seal with the sensor block when the drawer knob is turned to the READ position. Therefore, any sample material left on the cup rim will be transferred to the block, preventing this seal and contaminating future samples.

5. **If a sample will be read at some other time, put the sample cup’s disposable lid on the cup to restrict water transfer.** For long-term storage, seal the lid by placing tape or Parafilm™ completely around the cup/lid junction. It is necessary to seal the cup if it will be a long time before the measurement is made.
Samples Needing Special Preparation

AquaLab reads most materials in less than five minutes, depending on which mode you are operating in. Some samples, however, may require longer reading times, due to the nature of the material you are sampling. These materials need additional preparation to ensure quick, accurate readings. To find out whether special sample preparation is necessary, take a reading and see how long it takes to find the water activity. If it takes longer than six minutes, remove the sample and take a reading of a calibration standard. This will ensure that the sample itself is causing the long read time, and that there is not a problem with your instrument. If the calibration standard also takes longer than six minutes to sample, refer to Chapter 11 of this manual for more information.

Coated and Dried Samples

Samples with coatings such as sugar or fat often require longer reading times, because it takes longer for them to equilibrate. If this is the case for your samples, don’t worry that something is wrong with your instrument; it simply means that your particular sample takes longer than most to equilibrate water with its outside environment.

To reduce the time needed to take a water activity reading for coated or dried samples, one thing you can do is crush, slice, or grind the sample before putting it in the sample cup. This increases the surface area of the sample, thus decreasing reading times. Keep in mind, however, that modifying some samples may alter their water activity readings.

For example, a candy may have a soft chocolate center and a hard outer coating. The water activity reading for the center and the
AquaLab Pre
8. Sample Preparation

outer coating are different, so one would need to evaluate which part of the sample needed to be measured before crushing it. When the candy is crushed, for example, the water activity will represent the average water activity of the entire sample; whereas leaving the candy whole will give a reading for the coating, which may act as a barrier to the center.

NOTE: If you crush, grind, or slice your sample, be consistent in the method you use in order to obtain reproducible results.

Slow Water-Emitting Samples
Some extremely dry, dehydrated, highly viscous water-in-oil (butter), high fat, or glassy compositions may have increased read times, due to their moisture sorption characteristics. AquaLab may require up to ten minutes to reach an accurate measurement of water activity and nothing can be done to decrease the reading times of these types of samples.

For faster reading, it is important to have the water activity of the chamber at or below the water activity of these type of samples. This causes the sample to release water to the vapor phase and equilibrate with the chamber. If the water activity of the headspace is greater than this type of sample, a long period of time will be required to reach equilibrium and the water activity of the sample may be affected.

Volatile Samples
AquaLab will give accurate readings on most samples. However, samples with certain volatiles in high enough concentrations may give inaccurate water activity values. This is because the volatiles
condense on the mirror during the reading process, but do not evaporate from the mirror as water does. As a result, the reading on volatiles will not be accurate. The concentration of volatiles that will cause interference is variable and matrix dependent. The most effective method to determine if volatiles are a problem is to look for incorrect standard readings after reading the sample.

If you will be testing samples with volatiles on a regular basis that need a more accurate reading, you should consider upgrading to the Decagon’s Series 4TEV which is designed for measuring volatiles such as propylene glycol and ethanol. For more information about the Series 4TEV, contact Decagon Devices at support@aqualab.com or 509-332-5601.

**Low Water Activity**

Samples that have a water activity of less than about 0.03 cannot be accurately measured with the normal AquaLab Pre model. Samples with such low water activity values are rare. When a sample’s water activity value is below its ability to accurately measure, your AquaLab will display an error message indicating the last reading it could make on that particular sample. For example, say you are measuring a dry sample and the following screen appears:

\[
\begin{array}{c}
aw < 0.031 \\
24.7 \degree C
\end{array}
\]

This screen indicates that the last water activity reading the AquaLab measured on this sample was 0.031 at 24.7°C. Therefore, the actual water activity of the sample is lower than the instrument’s components can measure. If your sample is not extremely
AquaLab Pre
8. Sample Preparation

dry but is still getting the error message, refer to Chapter 11 for other possible explanations.

Samples not at Room Temperature
Samples that are 4 degrees colder or warmer than the instrument (chamber) temperature will need to equilibrate to ambient temperature before a fast, accurate reading can be made. Rapid changes in temperature over short periods of time will cause the water activity readings to rise or fall until the temperature stabilizes. When the temperature stabilizes within one or two degrees of the chamber temperature, you can proceed with normal measurements.

High-water activity samples that are warmer than the chamber temperature can cause condensation inside the measuring chamber, which will adversely affect subsequent readings. A warning message appears if the sample temperature is more than 4°C above chamber temperature.

If this message appears, immediately remove the sample from the instrument, place a lid on the cup, and allow the sample to cool to within 4°C of the instrument before measuring.

Samples that are lower than 4°C of the instrument’s temperature will cause long read times. The sample temperature must be within one or two degrees of the chamber temperature before fast, accurate readings can be made.
9. Taking a Reading

**Measurement Steps**

Once you have prepared your sample, you are ready to take readings. The process is simple:

1. Turn the sample drawer knob to the OPEN/LOAD position and pull the drawer open.

2. Place your prepared sample in the drawer. Check the top lip of the cup to make sure it is free from sample residue (remember, an over-filled sample cup may contaminate the chamber’s sensors).

3. Carefully slide the drawer closed, being especially careful if you have a liquid sample that may splash or spill and contaminate the chamber.

4. Turn the sample drawer knob to the READ position to seal the sample cup with the chamber. The following screen will appear:

   ![chamber sealed measurement started]

   This will start the read cycle. Length of read times may vary depending on temperature differences between the chamber and your sample, and other properties of your sample.
NOTE: Samples that have a large difference in water activity from previous samples may need extra time to reach equilibrium, since some of the previous sample’s atmosphere stays in the chamber after measurement.

**How AquaLab takes Readings**

AquaLab’s reading cycle continues until the rate of change of three consecutive readings are less than 0.0005 of each other. The instrument crosses the dew threshold numerous times to ensure the accuracy of readings. When the instrument has finished its read cycle, the water activity is displayed, accompanied by the LED flash and beeper (if you have the beeper enabled).

**Cautions**

- Never leave a sample in your AquaLab after a reading has been taken. The sample may spill and contaminate the instrument’s chamber if the instrument is accidentally moved or jolted.

- Never try to move your instrument after a sample has been loaded. Movement may cause the sample material to spill and contaminate the sample chamber.

- Take special care not to move the sample drawer too quickly when loading or unloading liquid samples, in order to avoid spilling.

- If a sample has a temperature that is four degrees higher
(or more) than the AquaLab’s chamber, the instrument will display a message (below)

```
sample too hot
```

alerting you to cool the sample before reading. Although the instrument will measure warmer samples, the readings may be inaccurate. Warm samples can cause condensation in the chamber if they have a high water activity.

- The physical temperature of the instrument should be between 4°- 50°C. Between these ambient temperatures, AquaLab will measure samples of similar temperature quickly and accurately.

- If you are sampling and a triangular warning symbol appears in the top right corner, this indicates that the

```
0.853 a_w  Δ
24.7°C
```

mirror has become too dirty to give accurate measurements, and you need to clean the mirror and chamber before continuing to sample. For more details about this symbol, please refer to Chapter 11. For cleaning instructions, refer to Chapter 6.
AquaLab Pre
9. Taking a Reading

• If a sample has a water activity lower than about 0.03, AquaLab will display a message, accompanied by the flashing light, notifying you that your sample is too dry to be accurately measured by the AquaLab. Following is an example:

\[
\begin{array}{c}
\text{aw} < 0.031 \\
24.7 \, ^\circ\text{C}
\end{array}
\]

This message will stay on the screen until you open the sample drawer. If you know that your sample’s water activity is above what the screen is telling you, your instrument’s sensors may have been contaminated and will need to be cleaned (see Chapter 6) or serviced (see Chapter 12).
10. Computer Interface

Your AquaLab Pre comes with a RS-232 to USB interface cable. Using this cable, you can connect to your AquaLab and send water activity data to a computer for further analysis and storage. The interface is run through the AquaLink 4 Software or a terminal communication program.  

**NOTE:** You can find the driver for this cable on our website at [http://www.aqualab.com/support/usb-cable-adaptor-driver](http://www.aqualab.com/support/usb-cable-adaptor-driver) or on the AquaLink trial CD included on the inside cover of this manual.

**AquaLink 4 Software**

An optional software program, AquaLink 4, is available for use with your AquaLab. AquaLink 4 is a Windows based program designed for data collection and customized report generation for all AquaLab models. AquaLink 4 logs water activity, temperature, time of measurement, and date stamps along with other information. AquaLink 4 also has sample identification and comment fields that you can use to help annotate the data your AquaLab is gathering.

A 30 day trial CD of this program is attached to the front cover of this manual. If you are interested in purchasing a license of AquaLink 4, contact Decagon or your local distributor. On the next page is a sample picture of the AquaLink 4 program:
Using a Communication Program

NOTE: If using the USB interface cable without AquaLink 4, you will need to install the driver for the USB interface cable. The driver can be downloaded from the trial CD included with this manual, or on our website at http://www.aqualab.com/support/usb-cable-adaptor-driver.

There are several terminal program options. Decagon has its own terminal program (DecaTerm) which can be downloaded from http://aqualab.com/software/DecaTerm.zip. Two other options are TeraTerm, which is a free program that can be found on the internet and Hyperterminal which came standard with Windows prior to Windows 7.
To use any of these terminal programs with your AquaLab, follow the instructions for the program with the following settings. Be sure to power on the AquaLab prior to connecting the USB interface cable to your computer.

- Choose correct Com port
- Set/Verify Com Properties
  - Bits per second 9600
  - 8 Databits
  - No parity
  - 1 stop bit
  - Flow control set to none

After successfully connecting the AquaLab to your computer and upon completion of a water activity reading, the data will be displayed in the terminal program in the format as follows: measurement time (minutes), sample temperature, and water activity. Here is an example:

$$3.1, 24.3, 0.862$$
11. Troubleshooting

AquaLab is a high performance instrument, designed to have low maintenance and few problems if used with care. Unfortunately, sometimes even the best operators using the best instruments encounter technical difficulties. Below is quick reference guide that will direct you to detailed solutions of some problems that may occur. If these remedies still don’t resolve your problem, then please contact Decagon for help (see Chapter 12: Support and Repair).

<table>
<thead>
<tr>
<th>Troubleshooting Quick Guide</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>If this problem occurs:</strong></td>
</tr>
<tr>
<td>AquaLab won’t turn on...</td>

</tr>
<tr>
<td>turning on AquaLab</td>
</tr>
</tbody>
</table>
PROBLEM #1:
AquaLab won’t turn on.

SOLUTION:

1) Check to make sure your power cord is securely attached to the back of the instrument and it is plugged in into the power outlet.

2) A power surge may have caused a fuse to blow. To change the fuses, follow these instructions:
   a. Unplug the power cord.
   b. Locate the panel where the power cord plugs in. The fuse box is on the right side of that panel. Press in on the release tab and pull the fuse-holder out. Pull the broken fuse(s) out and replace with a 1.25 Amp 250V fuse.
   c. Replace the fuse-holder and push it into the fuse-well until the release tab snaps in place.
   d. Re-connect the power cord and turn your instrument on. If the fuse blows again, a failed component may be causing the problem. Contact Decagon to make arrangements for repairs.

Caution: Do not use any other kind of fuse or you will risk damage to your instrument as well as void your warranty.
**PROBLEM #2:**
Readings are slow or inconsistent.

**SOLUTION:**

1) **The sample chamber may be dirty.** Refer to Chapter 6 of the manual for directions on cleaning the sample chamber.

2) **Some products absorb or desorb moisture very slowly,** causing measurements to take longer than usual, and nothing can be done to speed up the process. Refer to Chapter 8 for further explanation.

3) **Your sample may contain volatiles.** Volatiles are known to cause unstable readings, because they condense on the surface of the chilled mirror and alter readings. Please refer to the volatiles section in Chapter 8 for hints on reducing difficulties with measuring samples with propylene glycol. If you have further questions regarding the measurement of volatiles contact Decagon.

4) **A fan blade in the block chamber may be broken or bent.** If even salt standards take a long time to read, and the sample chamber is clean, you may have a broken chamber fan blade. This is especially likely if you have just cleaned the chamber. If you suspect this may have happened, contact Decagon for details on replacement.
**PROBLEM #3:**
Water activity readings on calibration standards are too high/low and a linear offset adjustment cannot be made any higher/lower.

**SOLUTION:**

1) The thermopile in your chamber, which measures sample temperature, may have become contaminated. Refer to Chapter 6 for directions on cleaning.

2) The chamber mirror may be dirty. Refer to Chapter 6 for directions on cleaning.

---

**PROBLEM #4:**
Message on screen displays the following:

```
sample too hot
```

**SOLUTION:**

1) Your sample’s temperature is too high for the instrument to equilibrate with it in a reasonable amount of time. The instrument and sample need to be in temperature equilibrium before accurate samples can be made. Therefore, very cold samples will take a very long time to measure for the same reason. To avoid this problem, make sure to only measure samples that are at the same temperature as the instrument.
AquaLab Pre
11. Troubleshooting

PROBLEM #5:
Message on screen displays the “<“ symbol.

\[ a_w < 0.028 \]

24.7 °C

SOLUTION:
1) The sample is too dry for the instrument to read accurately. If your sample has a water activity that is less than below the detection limits of the instrument, this message will come up. Essentially, it means that there is not enough sample moisture to condense on the mirror and provide a reading.

2) The mirror may be dirty. Try cleaning the mirror and chamber and measuring the sample again.

PROBLEM #6:
Message on screen displays “aw > 1.0....”

SOLUTION:
The Cooler is damaged and will need to be serviced by Deca-gon. See Chapter 12 for detailed instructions.
**PROBLEM #7:**

Verification is not correct.

**SOLUTIONS:**

1) **The sample chamber and mirror need to be cleaned.** See Chapter 6 for detailed cleaning instructions. If verification is still not correct, then linear offset has occurred.

2) **Verify and Adjust for Linear Offset.** After you have cleaned the sample chamber and mirror (Chpt. 6) you will need to use a Calibration Standard to verify and adjust for Linear Offset as described in Chapter 7.

**PROBLEM #8:**

A small triangle appears in the upper right corner after sampling:

\[ 0.853 \, \text{a}_w \quad \Delta \quad 24.7^\circ\text{C} \]

**SOLUTION:**

1) **The mirror needs to be cleaned**, along with the rest of the sample chamber, or a volatile contaminant is interfering with the dewpoint determination. This triangle is a mirror performance indicator. The performance of the mirror is measured
AquaLab Pre
11. Troubleshooting

on a 0 to 1 scale, with 1 being the cleanest. When the AquaLab senses that the mirror performance has dropped to unacceptable levels, it will display the triangular warning sign after the sample has been measured. To see what the mirror performance value is, press the upper right button when the triangle appears, and it will show you the value. At this point, you should stop sampling and clean the chamber. If the triangle is still on the screen after cleaning, the mirror is most likely still dirty or a volatile in your sample is contaminating the mirror. Contact Decagon for more assistance.

PROBLEM #9:
The following screen comes up after turning on the machine:

```
block failure
```

SOLUTIONS:

1) **The block is not plugged in to the motherboard.** Open the case and check to make sure that the small ribbon cable that connects the block to the motherboard is snapped and locked in place.

2) **One or more components has failed on the block’s circuit board.** If the block is properly plugged in to the motherboard and this message appears, it is likely that one or more of the components have failed on the block’s circuit board. If you
press -exit- at this prompt, the instrument will not have values for the component that has failed, which will lead to incorrect readings. If this message appears and you continue to sample, Decagon cannot be liable for errors in reading that may occur. Contact Decagon for a solution to this problem.

**Component Performance Screen**

If, after cleaning your instrument and reading the other troubleshooting hints, you have reason to believe that one of the components of your AquaLab may be causing measurement error, you can access a screen that will display values for component performance. This is done either by holding down the lower right button while turning on the instrument, or by first pressing the lower left button (system configuration menu), then the upper right button (linear offset menu) and then the upper left button.

The following screen will appear:

```
sensors  3.21  0.030
-Exit-   23.5  1100
```

This screen gives you four values. The top left value is the value the thermocouple is reading. It is basically the difference in temperature between the block and the mirror. It should typically have a value of 3, ±0.3. If this is zero, there is something wrong with the thermocouple. The top right value is the value read by the thermopile, which is the temperature difference between the block and
what it “sees” below it (the sample, when reading). This value should be around zero, but will change when you change the drawer position. The bottom left value is the block temperature. This value should be around ambient temperature. The bottom right value is the mirror reflectance voltage, in units of millivolts. This value should normally be between 400 and 2400mV, and should be steady.

You can’t change anything in this screen, but it is here to give you an indication of the component performance. If you notice that any of these values are not what they should be, contact Decagon for further instruction. Press the button next to -Exit- to get back to the main menu.
12. Support and Repair

NOTE: If you purchased your AquaLab from one of our international distributors, please contact them. They will be able to provide you with local support and service.

When encountering problems with your AquaLab (that can’t be resolved with the help of this manual), please contact Decagon Customer Support at support@aqualab.com, 509-332-5601 or fax us at (509) 332-5158. Please have the serial number and model of the instrument ready.

All AquaLabs returning to Decagon for servicing must be accompanied with a Return Material Authorization (RMA) form. Prior to shipping the instrument, please contact a Decagon customer support representative to obtain an RMA.

Shipping Directions:

The following steps will help to ensure the safe shipping and processing of your AquaLab.

1. Ship your AquaLab in its original cardboard box with suspension packaging. If this is not possible, use a box that has at least 4 inches of space between your instrument and each wall of the box.

2. Place an empty sample cup in the sample drawer to help protect it from damage during shipping.
**AquaLab Pre**

12. **Support and Repair**

3. Place the AquaLab in a plastic bag to avoid disfiguring marks from the packaging.

4. **Don’t ship the power cord or serial cable.**

5. If the original packaging is not available, pack the box moderately tight with packing material (e.g. styrofoam peanuts or bubble wrap), ensuring the instrument is suspended in the packing material.

6. Include a copy of the RMA form in the shipment. Please verify the ship to and bill to information, contact name, and problem description. If anything is incorrect, please correct it on the RMA form or contact a Decagon representative.

7. Tape the box in both directions for added support.

8. Include the RMA number in the attention line on the shipping label.

**Ship to:**

Decagon Devices Inc.

ATTN: RMA (insert your RMA #)

2365 NE Hopkins Court

Pullman, WA 99163

**Repair Costs**

Manufacturer’s defects and instruments within the one-year warranty will be repaired at no charge. Non-warranty repair charges for parts, labor and shipping will be billed to you. An extra fee may be charged for rush work. Decagon will provide an estimated repair cost, if requested.
Loaner Service

Decagon has loaner instruments to keep you measuring water activity while your instrument is being serviced. If your AquaLab is still under calibration warranty or you have a service plan with your instrument, there is no charge for the loaner service.

Appendix A

Preparing Salt Solution

If you choose to mix a saturated salt solution for use as a calibration standard, we recommend that you use the approved AOAC method. This method is as follows:

1. Select a reagent-grade salt and place it in a test container to a depth of about 4cm for more soluble salts (lower water activity), to a depth of about 1.5 cm for less soluble salts (high water activity), and to an intermediate depth for intermediate salts.

2. Add distilled water in increments of about 2mL, stirring constantly.

3. Add water until the salt can absorb no more water, evidenced by the presence of free liquid. Keep the amount of free liquid to the minimum needed to keep the solution saturated with water. If you plan on using this solution over a long term period, seal the solution well to prevent losses from evaporation. Below is a table of saturated salt solutions and their respective water activities at various temperatures. Please note that these values are based on averaged published data, and the standard errors shown reflect Greenspan's standard error for each salt solution, not the AquaLab's accuracy in measuring the salt. AquaLab measures all samples with an accuracy of ±0.01a_w.
4. Saturated salt solutions are very temperature-sensitive and their values are not as accurate as the calibration standards offered by Decagon.

**Table 1: Water Activity of Selected Salt Solutions**

<table>
<thead>
<tr>
<th>Saturated Solution</th>
<th>$a_w$ at 20° C</th>
<th>$a_w$ at 25° C</th>

Declaration of Conformity

Standards to which conformity is declared:
EN81-1
EN500082-1

Manufacturer’s Name: Decagon Devices, Inc.
2365 NE Hopkins Court
Pullman, WA 99163
USA

Type of Equipment: AquaLab water activity meter.

Model Number: Pre

Year of First Manufacture: 2012

This is to certify that the AquaLab water activity meter, manufactured by Decagon Devices, Inc., a corporation based in Pullman, Washington, USA meets or exceeds the standards for CE compliance as per the Council Directives noted above. All instruments are built at the factory at Decagon and pertinent testing documentation is freely available for verification.
Certificate of Traceability

Decagon Devices, Inc.
2365 NE Hopkins Court
Pullman WA 99163
tel: (509) 332-2756
fax: (509) 332-5158
support@aqualab.com

This is to certify that AquaLab water activity meters are manufactured utilizing temperature standards with calibration traceable to the National Institute of Standards and Technology (NIST).
